In the design of novel nuclear reactors active systems are replaced by passive ones in order to reduce the risk of failure. For that reason natural circulation is being considered as the primary cooling mechanism in next generation nuclear reactor designs such as the natural circulation boiling water reactor (BWR).

The stability of natural circulation boiling water reactors is investigated with a strong emphasis on experiments. Two different facilities are used for such a task: the GENESIS facility (to which a void reactivity feedback system is artificially added) and the CIRCUS facility. In addition, numerical codes are also used in the investigation.

Various experimental and analytical studies devoted to natural circulation behavior of economic simplified boiling water reactor (ESBWR) are presented, e.g. by Manera and Van der Hagen (2003) and Rohde et al. (2010), emphasizing that well-defined startup procedures are needed to cross the instability region during the transition from single-phase to two-phase flow operation.
